

CONDUIT

Money that follows a rule you signed once —
without giving anyone your keys.

LIVE ON TESTNET

conduit-psi-three.vercel.app

The Solution

Automation and custody arrive as a package. **Conduit separates them.**

WHY A CONTRACT — WE BUILT THE FIRST TWO OURSELVES

v1 • Fund a bot

Give it a budget and it trades. Nothing on chain caps what it does with that budget, and the money already left your wallet.

Still how buy & sell runs today, on a budget you set aside.

Approve the bot

A token allowance caps the amount and nothing else. Which asset, at what price, how often — all of it stays a promise made off chain.

v2 • Classic multisig

Thresholds are per operation *category*, not per amount or asset. And 2-of-2 needs your signature on every trade, which defeats automating.

v3 • So: a mandate

A Soroban contract holds the rule — assets, cap per window, price bounds, expiry — and the allowance goes to *it*, never to the bot. A **stolen bot key cannot steal**: theft needs a recipient, and the recipient is not a parameter.

```
transfer(&contract,  
        &owner,  
        &amount_out)
```

PMF

Earning in one currency and living in another is a decision you have to take again every week — and being late costs real money.

The same decision, again

Convert now or wait. Keep a share in dollars. Cash out at a rate. Every payment reopens all three, and the answer is usually the same one as last month.

Someone has to be there

Acting on it means opening a wallet, at a moment nobody chose. Waiting for a better rate only works if you are watching when it arrives.

The fix asks for too much

Everything that would do it for you wants custody first — an exchange holding the balance, or a bot holding the key. Most people decline, and the money sits still.

ONE RULE, ONCE

100 USDC arrives → 40% XLM · 30% AQUA · 30% stays in dollars — every time, without anyone being there. *An example rule, not advice.*

Who feels it first: freelancers and exporters invoicing abroad, households on remittances, businesses taking stablecoin payments — and anyone whose savings lose value while they wait for a good moment to act. **The alternative to automating is not inaction; it is worse decisions.**

Our hypothesis is that bounded automation is worth repeating. The next step is a small pilot measuring setup completion and repeat use — not a claim that it is already proven.

Technical Workflow

Two phases. The owner is in the first and absent from the second — **that gap is the product.**

PHASE 1 · SIGNED ONCE

PHASE 2 · NO SIGNATURE FROM THE OWNER

Portfolio mode — under the mandate. Your funds never leave your wallet.

Buy & sell — a funded automation wallet. Outside the mandate today.

The buy is one transaction, not three. The contract pulls the USDC on the allowance, swaps through Soroswap and forwards the result — if any part fails, nothing moved.

LIVE NOW

conduit-psi-three.vercel.app · mandate contract

CAAPS6MYLC2DQ4TPOCRDKBCG4HVSQ35P4PCGQ7LAIISHQSPCP4RJ7DPO on testnet, enforcing assets, cap, price bounds and expiry · 17 contract tests · every leg verifiable on stellar.expert

Architecture

The whole client runs in the browser. Everything that can move money runs on chain. **Nothing of ours sits in between** — we operate no service that holds a key or a balance.

In your browser

The whole client. No server of ours holds a key or a balance.

automation.ts — watches Horizon by cursor, decides, clamps to the cap

mandate.ts · **anchor.ts** — the contract client and the whole SEP surface

secure-key.ts — the automation key, non-extractable, in IndexedDB

passkey.ts — WebAuthn PRF to Ed25519, re-derived for every signature

On Stellar

The only place a rule is actually enforced.

Mandate contract — cap per window, price bounds, one delegate, fixed recipient

USDC SAC — the allowance, granted to the contract and never to the bot

Soroswap router — the swap, called by the contract rather than by us

Horizon — incoming payments, read by cursor every 15 seconds

Outside

Standards, not integrations — any SEP-6 anchor fits.

Anchor — SEP-1, 10, 12, 6, 38. Lira in, lira out

Your bank — TRY by IBAN, in both directions

Reflector — SEP-40 rate, shown beside the pool price, never traded on

Route handlers — Telegram and model proxies. Secrets only, never funds

THE MONEY PATH

Your wallet → allowance → mandate contract → Soroswap → your wallet

The automation key is nowhere on it. It signs a request; the contract decides whether to honour it, pulls from the allowance itself, and sends the result to an address it reads from its own storage.

The Team

MK

Murat Keskin

Project author — Soroban contract, rule engine, anchor integration, interface.

Wrote the mandate contract and its 17 tests, the SEP-1/6/10/12/38 client, the browser watcher that triggers rules, and the passkey sign-in that removes the wallet extension.

ROADMAP

Keepers, so rules survive a closed laptop · per-asset price bounds in the mandate · a production anchor, then more corridors
